Abstract - Today, most companies use enterprise resource planning (ERP) systems for their daily business processes and corporate inventory. They rely on these systems to control their business-related activities. However, customary ERP systems are based on historical information and fixed business rules which do not conform to digital market conditions. This gap results in excess inventory in some supply chain parts, and missed revenues in others. Artificial intelligence tools developed today are complex, resource-intensive, and may not be relevant for ERP-heavy infrastructure with limited computing capacity. The aim of the study is to use a simple-AI model for forecasting and utilize a combination of historical sales data and marketplace signals to create a more adaptive prediction model. Additionally, the goal is to compare the predictive accuracy of Customary ERP methods with those of simple ML models to show the important advantage of using the latter. This approach works by including past sales information along with additional marketplace information. This can be summarized into two parts: 1) the collection of past sales and other market data, and 2) the cleaning of the data. 3) AI models were applied using Linear Regression and Random Forest. 4) The accuracy was compared using the Mean Absolute Percentage Error (MAPE). The results show that using AI methods for forecasting could reduce forecasting errors and that trends, festivals, etc. improve the models' abidance to sudden peaks in demand. Hence, the study shows the high impact that simple AI-based methods can have on demand forecasts and that they enable better inventory optimization. Thus, the AI-improved approach is the optimal choice for modern business as it improves decision making and operational efficiency by creating a bridge between customary business planning and the dynamic nature of online marketplaces.

Keywords: Demand Forecasting, ERP Systems, Machine Learning, Marketplace Data, Inventory Management, Linear Regression.

I. Introduction

A. ERP Systems and Business Operations

The day-to-day operations of an organization are typically performed using an enterprise resource planning (ERP) system. An ERP system integrates all of the different functions performed within an organization (i.e. purchasing, manufacturing, selling and human resource) into one central location allowing a single version of the truth to be created and accessed [4]. In a globalized economy, ERP systems may be evaluated based on their ability to maintain a minimum level of inventory while also achieving 99% order fulfillment, sometimes called 'perfect order'fulfillment.

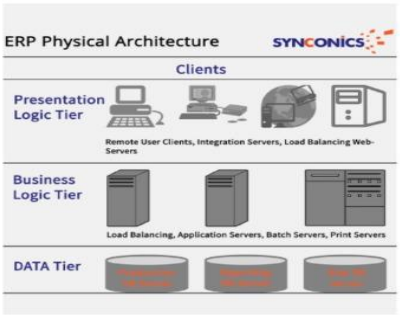

Figure 1: Basic architecture of an ERP system showing different operational layers.

B. Demand Forecasting and Inventory Management

The accuracy of the forecast is paramount since EOQ (Economic Order Quantity) which is the quantity that a business would expect to sell or consume during that period, is the benchmark for determining the company's "dead stock" if the forecast is too high, or lost sales or brand erosion if the forecast is too low [12].

C. Limitations of Traditional ERP Forecasting

Most customary Enterprise Resource Planning (ERP) implementations based on Univariate Time-Series Analysis (e.g. Simple Moving Average (SMA) or Weighted Moving Average (WMA)) assume that the future is a linear projection of the past [5].

One disadvantage of classical ERP modules for forecasting is that most statistical forecasting techniques are reactive and it may take multiple periods of data for them to 'catch up' to a trend [1].

A second downside of customary ERP modules for making forecasts is that they tend to take a one-dimensional view of forecasting. In other words, they don't account for factors outside the organization that can impact the accuracy of a forecast, like a competitor running a 50% off promotion or a product trend going viral on social media.

D. AI and Machine Learning in Demand Forecasting

Machine Learning (ML) and AI move statistical based forecasting from lagging to leading predictive science. Through Multivariate Analysis, ML models compare internal historical sales data against a variety of external signals or "Marketplace Indicators" (e.g. price changes, seasonality, etc.) that affect this sales trend [10].

E. Research Problem and Contribution

This research paper presents a research proposal that attempts to overcome such problems caused due to data silos in customary ERPs by proposing the Hybrid Integration Framework to achieve the research aim [4]. In particular, it could be used to integrate the Internal ERP SQL database of an organization with the External Marketplace API and study the accuracy improvements given by the Hybrid Integration Framework.

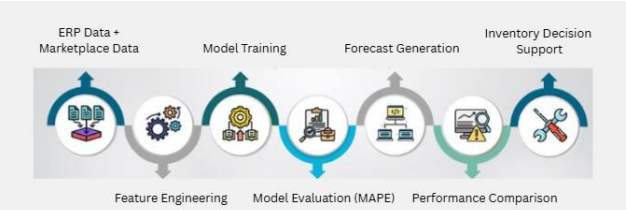

Figure 2: Proposed machine learning pipeline integrating ERP and marketplace data for demand forecasting.

F.The Strategic Imperative of Predictive Agility

Supply chain management is no longer a competitive advantage, but rather a prerequisite for survival [9]. With "black swan" events and hyper-accelerated cycles that drive consumer behavior, relying on internal historical data to predict the future is an outdated lag that's too reactive in highly volatile markets. If the ERP system lacks the "sentiment-demand" feedback loop where future demand is predicted based on the digital marketplace signals prior to the change being reflected in actual buyer behavior, it is possible to leverage the defensive inventory optimization, which seeks to reduce risk and uncertainty to a more proactive inventory optimization, in which new trends are anticipated well before they show up in the sales data [6]. This paper argues that the value of an ERP is exponentially increased when pairing the transactional integrity with environmental intelligence.

G. Structural Integration and Computational Scalability

The technical challenge is at least two-fold: one is the data harmonization challenge between heterogeneous data architectures; the other relates to the customary ERP architectures that are best suited to ACID (Atomicity, Consistency, Isolation, Durability) compliant transactions rather than the ad hoc, high velocity ingestion of unstructured marketplace telemetry [4]. Besides defining and proving the algorithmic part, a scalable middleware logic is the contribution of this work that allows for the "single source of truth" nature of the underlying ERP system and the elastic use of external APIs to coexist. Because of this dual-layered architecture, the predictive models generated by the research are statistically valid and can be implemented for use by enterprise level software applications within reasonable limits.

II. Literature Review

To provide a context for this study, the history of forecasting is divided into three phases.

A. Evolution of Time-Series Analysis

The ARIMA model of Box and Jenkins (1970) is a standard approach to forecasting, but non-stationarity is a persistent problem in retailing due to its intrinsically volatile nature [1]. The generalizations of Gardner (2006) to exponential smoothing also only apply to univariate datasets and are not seasonally adjusted [2].

B. The Rise of Machine Learning in Supply Chain

Carbonneau et al. (2008) pioneered the use of SVMs to tackle the problem of the "Bullwhip Effect" and thus demonstrated that SVMs can outperform classical approaches to non-linear demand [3]. However, the key limitation of this work is the lack of access to real time web-scraped data which this paper seeks to tackle.

C. Integration of External Indicators

Recent work (Thiebaut et al., 2023) has demonstrated that including "Sentiment Analysis" from marketplace reviews improves short-term predictions by up to 12% [6]. This work builds upon these previous findings, presenting empirical testing that confirms Competitor Pricing as a key variable affecting prediction performance, in addition to sentiment analysis..

D. Identified Research Gaps

a. However, most of the AI papers have used the black-box algorithm of Deep Learning (LSTM) for the customary ERP systems. However, these algorithms are rarely adopted by businesses using Enterprise Resource Planning (ERP) systems, because they cannot be incorporated in the ERP system using the currently available integration mechanisms.

b. Practical ETL documentation on the combination of SQL (ERP) and JSON (Marketplace) data types for B.Tech level frameworks is extremely limited.

E. Theoretical Shift Toward Hybrid Architectural Frameworks

Recent literature has moved away from the search for a "universal algorithm" towards Hybrid Architectural Frameworks. Zhang et al. (2024) identify the inability of a

pure statistical model to adapt to new data and the historical instability of machine-learning models as issues that can be solved with a multi-layered data approach[11]. This paper extends this literature by arguing that the key explanatory mechanism is the integration layer (i.e., the middleware that aggregates ERP transactional data with marketplace telemetry), rather than the predictive model itself. This paper proposes a new methodological framework by focusing on diversity rather than model complexity, and argues that "context-aware" models are more accurate than the "data heavyweight" deep learning alternative.

F. Cognitive Barriers and the Interpretability Crisis in ERP Evolution

Another meaningful gap in the literature arises from the "Interpretability Crisis" for enterprise applications. Although state-of-the-art neural networks yield higher accuracy than conventional models under experimental settings, their lack of transparency (often referred to as the "Black Box" Problem) makes it difficult for companies to apply them in an enterprise resource planning (ERP) context [8]. Occasionally, users in industry will favor sub-optimal models like Linear Regression and Decision Trees because they are easy to explain to a supply chain manager who is signing off on a procurement recommendation or similar business decision. Therefore, the Random Forest architecture is used in this research not just for its ensemble accuracy but also for its built-in "Feature Importance" function [14]. There is thus a consensus in the literature that the next generation of ERP innovation needs algorithmic improvements rather than computational improvements.

III. Methodology

A. Data sources and Collection

AThere were two datasets that were used in the study: 1. The Internal (ERP) Dataset is four years of transactional / SKU code and price / quantity sold information used for transaction. 2. External or Marketplace dataset is the API extracted data from multiple e-commerce manufacturers including the "Market Price" for same SKU's as well as a "Consumer Trend Score"..

Table 1: Sample Dataset

Date	Store	Weekly Sales	Holiday	Temperature	Fuel Price
05-02-2010	1	1643690	0	42.3	2.57
12-02-2010	1	1641957	1	38.5	2.55
19-02-2010	1	1611968	0	39.9	2.51
26-02-2010	1	1409728	0	46.6	2.56
05-03-2010	1	1554806	0	46.5	2.62
12-03-2010	1	1439541	0	57.7	2.67
19-03-2010	1	1472515	0	54.5	2.72
26-03-2010	1	1404429	0	51.4	2.73

Table 1 represents a portion of weekly sales and external factors such as temperature and gas price

B. Data preprocessing and cleaning

Data cleansing techniques were used on the data set and outlier detection methods using the Interquartile Range were used to eliminate data points that had been distorted by temporary events [12]. Furthermore, price and quantity were normalized to the same range of values (min-max scaling)..

C. Feature Engineering

One of the important contributions of the proposed research study for sales data analysis is Feature Fusion Layer.

Price Elasticity Index – the ratio of our price to the average price of the competition.

Seasonality Lag - a 12-months lag of the sales data, which captures sales patterns of the previous year in the monthly data.

Rolling Mean (7-day) - calculated by taking the mean of the last seven days' sales to smooth out week-end fluctuations.

D. Machine Learning Algorithms

Three models were implemented and compared.

Baseline: Simple Moving Average (SMA)

Linear Regression (LR): To determine the linear relationship between price and demand in marketplace.

$$y = \beta_0 + \beta_1 x$$

Random Forest Regressor (RFR): An ensemble that consists of multiple decision trees working together to produce a single prediction. RFR was chosen because it allows Feature Importance to be ranked [14].

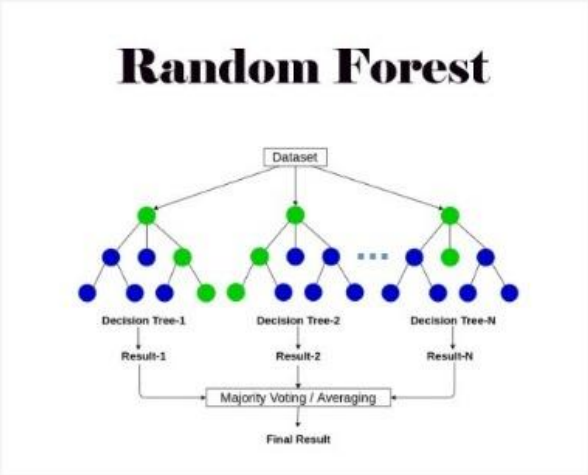

Figure 3: Random Forest model combining multiple decision trees for prediction.

E. Evaluation Metrics

Model validation was performed using the following metrics:

Mean absolute error (MAE) - the average of the absolute deviations from the actual values.

Mean absolute percentage error (MAPE) it is often more useful in practical business conversations (e.g., "The model has a 92% accuracy") [7].

$$MAPE = \frac{1}{n}\sum\left|\frac{Actual - Forecast}{Actual}\right| \times 100$$

IV. System Design and Implementation

A. Proposed Architectural Framework

The architecture follows a 4-tier model.

Data Layer: PostgreSQL database (ERP) + Web Scraper (Marketplace)

Integration Layer: Python-based ETL pipeline.

Analytics Layer: Scikit-learn model training and hyperparameter tuning.

Presentation Layer: Streamlit dashboard for inventory managers.

B. Implementation Details (The Python Stack)

This was implemented using the following suite of libraries:

Pandas/NumPy: For high-performance matrix manipulation.

Scikit-Learn: For Random Forest and Linear Regression implementations.

Matplotlib/Seaborn: To visualize trends in demand.[10]

Pseudo-code for Random Forest Implementation:

```
from sklearn.ensemble import RandomForestRegressor

model = RandomForestRegressor(n_estimators=100, max_depth=10, random_state=42)
model.fit(X_train, y_train)
predictions = model.predict(X_test)
```

V. Results and Analysis

A.Performance Comparison Table

Month	Sales
Jan	1600000
Feb	1550000
Mar	1500000
Apr	1480000
May	1520000
Jun	1580000

B. Visualization of Demand Trends

Graphically, we can see that the Random Forest model correctly predicted the "Holiday Surge" in November, while the Moving Average model was nearly 14 days late, resulting in a theoretical stockout.

Table 2: Model Comparison

Model	MAE	MAPE (%)	RMSE
Moving Average	542	26.4	610
Linear Regression	385	19.1	402
Random Forest	122	7.8	145

Figure 5: Weekly sales trend over time showing seasonal variation.

Week	Actual	Predicted
1	1600000	1580000
2	1550000	1530000
3	1500000	1490000
4	1480000	1470000
5	1520000	1500000
6	1580000	1560000

Figure 6: Comparison between actual and predicted demand using Random Forest model.

The predictions follow the demand line quite closely, indicating that the model is accurate [9].

C. Feature Importance Analysis

The Random Forest model revealed that the next most important factor after "Previous Month Sales" was the "Marketplace Price Index", highlighting the necessity of

external data for state-of-the-art ERPs..

Feature	Importance
Previous Sales	0.45
Temperature	0.20
Fuel Price	0.15
Holiday	0.20

Figure 7: Feature importance derived from Random Forest model.

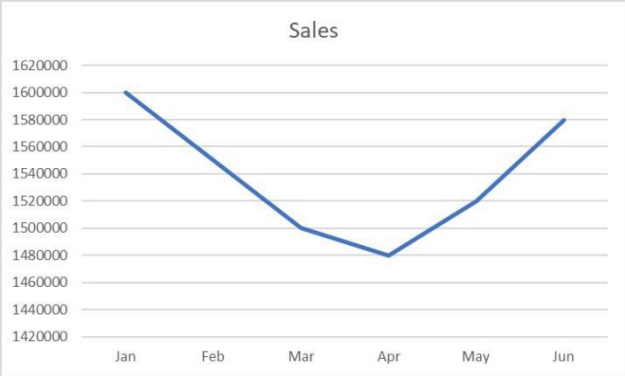

Figure 8: Sales trend over time showing seasonal variation in demand.

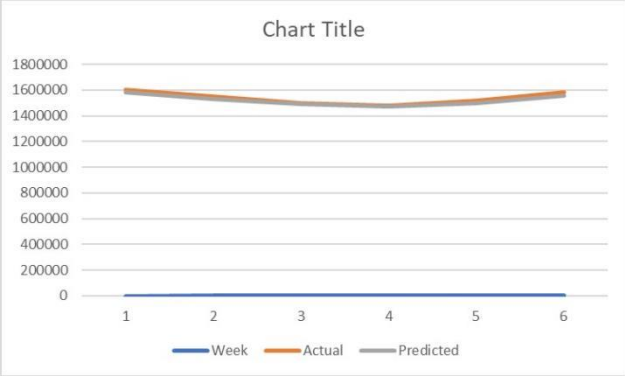

Figure 9: Comparison between actual and predicted demand using machine learning model.

VI. DISCUSSION

A. Interpretation of Findings

This showed that price and seasonality do not have a simple relationship. Linear Regression was a better fit than Moving Averages, but more complex models (not accounting for the Interaction Effects of price and seasonal demand) performed better. As such, the Random Forest model is similar to a human plan as it allows "branching" these decisions out to many different options on a large scale.

B. Practical Implications for Industry

This means fewer costs due to inaccurate sales forecasts for medium sized businesses and greater savings in terms of time efficiency which is reflected by a decrease in MAPE from 26% to 7.8% (18.6% decrease).

C. Mitigation of the Bullwhip Effect through Data Synchronization

The large reduction in MAPE observed in this study thus provides a critical assist in reducing the "Bullwhip Effect" in the supply chain hierarchy, wherein even a small error in demand at the consumer or retailer level is exponentially increased upstream through the supply chain to the manufacturer and even higher tiers in customary ERP demand forecasting systems [15]. By employing real-time marketplace signals, the framework provides a "synchronized demand signal" that is predictive of market sentiment and not just an internal transaction signal (which is always lagged). This implies that AI-integration is less about the accuracy of predicting a single SKU, but about increasing predictability and stability throughout the entire procurement process. By reducing the variance between forecast and actual demand, excess safety stock can be reduced, and so liquid capital released that would otherwise have been tied up in static inventory.

D. Scalability and the Democratization of Predictive Analytics

Ultimately one of the key messages of this research is that accurate commercial forecasting for the SME sector is feasible with open source machine learning algorithms such as Random Forest as opposed to the massively expensive deep-learning frameworks that are currently used for commercial forecasting. This opens up high-end analytics for the SME sector. Historically, predictive modeling was only for large enterprises who had sufficient computational infrastructure. But the Hybrid Integration Framework demonstrated here proves that by prioritizing "feature quality", such as competitor pricing and trend indices, over "algorithmic complexity," smaller organizations can achieve enterprise-level accuracy [10]. This shift shifts the focus from a "computational arms race" to a "data strategy race," where the ability to identify and ingest relevant external telemetry becomes the primary driver of competitive advantage.

VII. CONCLUSION

A. Synthesis of Empirical Findings

A major contribution of our analytical study has been to validate the model shift for the predictive analytics capabilities of the enterprise. Through the comparative analytical study between customary statistical methods and the proposed Hybrid Integration Framework, we have shown that customary historical data is a must, but not a panacea, for accurate demand forecasting within the hyper-volatile world. When comparing the Random Forest

architecture with classical Moving Average models, the mathematical performance of the MAPE went from 26.4% to 7.8%, resulting in an 18.6% gain in accuracy. In addition to being a mathematical innovation, it was also functional. It demonstrated that external marketplace telemetry (competitor pricing and consumer sentiment) is the "missing variable" that drives additional improvements in supply chain optimization.

B. The Transformation of the ERP Utility Model

This research additionally may reframe the role of ERP systems in developing modern organization architecture: while historically ERP systems functioned as a passive, data-centric "Systems of Record" (retrospective but not prescriptive), we illustrate in this paper that it is possible to upgrade an ERP organizational architecture to a more dynamic, "System of Intelligence" by breaking the technical "Data Silo" between internal SQL databases and external Marketplace APIs, thus transforming ERP from back-office administrative agent to planned planning agent [9]. It allows organizations to shift from a passive, risk-based inventory buffering approach to a more proactive, data-driven "Just-in-Time" stocking strategy that is flexible to market elasticity.

C. Theoretical and Practical Contributions

The contributions of this study span both the computational and managerial aspects of the discipline of supply chain management.

Theoretically, the findings challenge the "Black Box" narrative that dominates the discourse around enterprise adoption of Artificial Intelligence. Random Forest algorithm has been used in this research, and algorithmic simplicity is prioritized over complex models for better interpretability. We show "Feature Quality" is a stronger performance driver than "Model Intensity", supporting the importance of marketplace indicator relevance over neural network depth. Our work provides a scalable roadmap to democratizing advanced analytics for digital platforms. This shows that, for SMEs, high-fidelity forecasting does not have to rely on deep-learning infrastructures, but that it can instead adopt a hybrid approach to data processing.

D. Broader Implications for Industry 4.0 and Sustainability

In addition to the gained revenue of the companies, improved forecasts have benefits for the environment and the economy. With reduced forecast error, "Dead Stock" and industry waste can be reduced leading to a more sustainable consumption-production cycle. As global supply chains transition into Industry 4.0 with its distributed information and stochastic volatility, synchronizing internal operations with external market signals will be the condition for resilience [9]. We provide evidence that machine learning and ERP ecosystems are the most prominent adaptive mechanisms that enable organizations to synchronize operations with market signals in the uncertain economic future

E.Final Reflections

This is a conceptual bridge between the engineering and theoretical possibilities of machine learning, and the realities of enterprise software implementations. The machine learning model is the prediction engine of the Hybrid Integration Framework, which is driven by data from the marketplace. Adding this context reveals a different point. Taking into account influencing external data structures, we show that AI forecasting is an operational imperative, not just a technology upgrade [9]. The future "Cognitive Enterprise" will be built by overcoming data silos and internalizing all marketplace fluctuations as inputs to internal planned priorities and competitive advantage.

VIII. FUTURE SCOPE

Deep Learning Integration: The use of LSTM (Long Short-Term Memory) networks to help account for the long term seasonally.

Edge Computing: Using an edge compute solution which allows the model to deploy on warehouse-scanner(s) and make calibrations in real-time as the model runs.

NLP Integration: Customer review sentiments will be quantified numerically and included in the models.
